Egyptian Academic Journal of Biological Sciences is the official English language journal of the Egyptian Society for Biological Sciences, Department of Entomology, Faculty of Sciences Ain Shams University. Entomology Journal publishes original research papers and reviews from any entomological discipline or from directly allied fields in ecology, behavioral biology, physiology, biochemistry, development, genetics, systematics, morphology, evolution, control of insects, arachnids, and general entomology.

Anobium punctatum

INTRODUCTION

ABSTRACT

Two subfamilies of Egyptian Ptinid were taxonomically studied during this work, the first subfamily Dorcatominae represented by one species, *Synanobium parmatum* and the second subfamily Anobiinae represented by five species, *Oligomerus ptilinoides*, *Stegobium paniceum*, *Gastrallus pubens*, *Nicobium castaneum*, and *Anobium punctatum*. A key to the species together with diagnostic characters and illustrations are given for each species

Family Ptinidae (or Anobiidae is known the deathwatch beetle) is member of Bostrichiformia, is a worldwide distributed, represented by approximately 250 genera, about 2800 species, present in different habitats, from forest to steppe, where they develop in living or dead tree or shrubs (in wood and trunk of stems, branches and roots), in fungi or in other plants; some species are synanthropic, Zahradník, (2009). The most ptinids feed on accumulated dried animal or plant material, Howe (1959). Some species are common bird or mammal nest inhabitants, also some species found in solitary bee nests, where they feed upon pollen stores, Linsley, and MacSwaine (1942). Others commonly breed in dung while at least one species is a leaf miner, Philips, *et al.* (1998). When in houses and other buildings, the larvae live in many sorts of dried vegetable or animal substances, such as stored flour, wool, and similar products, Hinton (1941), and Howe (1959). Some ptinids pupate within cocoons formed from their peritrophic membrane, Tristam (1977). The larvae bore in bark, dry wood, twigs, seeds, woody fruits, galls, and fungi, or more rarely in the young stems or shoots of growing trees, the species *Anobium punctatum* causes great damage to furniture, the woodwork of houses, book bindings, and similar products, also species *Stegobium paniceum* (L.), the drug store beetle, harass the home-owner by breeding in stored products, tobacco, spices, and even cayenne pepper, Philips (2002).

The drugstore beetle, *Stegobium paniceum* (L.), is a serious pest of a great variety of stored organic materials of plant and animal origin, including drugs, tobacco, seeds, spices, cereal products, leather, and museum specimens. Larvae of most of the species for which the habits are known bore into dead hardwoods and softwoods; some of them, as the furniture

beetle *Anobium punctatum* (DeG.), damage woodwork and structural wood of buildings. The beetles often produce a tapping sound in their burrows, superstitiously interpreted as a warning of death, which is the basis for the common name, deathwatch beetles. Larvae of several species feed in various kinds of fungi. Some species feed in cones of conifers, some in twigs or vines, others in seeds, some in plant stems, a few in bark of various trees, and a very few have been bred from galls, White (1982).

MATERIALS AND METHODS

The present taxonomic work started by examining the Egyptian reference insect collections for material to obtain a general knowledge of the diversity and distribution of pitinids beetles in Egypt. These collections are: Alfieri collection, Faculty of Agriculture, Al-Azhar University (ALFC), Ministry of Agriculture collection, Plant Protection Research Institute (MAC), Ain Shams University collection, Department of Entomology, Faculty of Science (ASUC) and Cairo University collection, Department of Entomology, Faculty of Science (CUC). A field survey of pitinids beetles was carried out to cover practically different geographical localities of Egypt.

Examination and illustrations of the external features of specimens were achieved using M6C-9 (made in USSR) stereo binocular microscope. All drawings were made by a square eyepiece. The ocular micrometer was used in making measurements. The source of local distribution for each species is based on the material examined and published data. Total length (TL) of specimens is here defined as the distance between anterior margin of clypeus and posterior apex of pygidium. Pronotal length (PL) is the distance between anterior and posterior margins of pronotum. Pronotal width (PW) is the distance between the lager points of lateral margins of pronotum. Elytral length (EL) was considered the distance between posterior apex of scutellum and elytral distal apex. Elytral width (EW) is the distance between the lager points of lateral margins of elytra.

Mounting of specimens preparation with drawing of some species was made in the laboratory of insect research, Plant Protection Department, College of Agriculture, Al-Azhar University.

The taxonomic keys used in identification, terminology used in species descriptions and nomenclature and the systematic adopted are according to Fall (1905); Sharp, and Muir (1912); Forbes (1922, and 1926); Blackwelder (1945); Hatch (1961); Lawrence, and Reichardt (1966); Spilman (1975); White (1982); McNamara (1991); Lawrence, and Newton (1995); Downie, and Arnett (1996), and Philips (2000).

RESULTS AND DISCUSSION

Family Pitinidae Latreille, 1802

Diagnosis: Body strongly convex, elongate and cylindrical to oval; length 1.1 to 9.0 mm; color red, brown or piceous, some with lighter patches of setae or scales in various patterns; vestiture fine, mostly recumbent and / or erect. **Head** deflexed, inserted into prothorax, in some covered by pronotum; surface smooth, punctate, or rugose. **Antennae** with 11, 10 or 3 antenniferous clubs, the last 1, 2 or 3 segmented clubs, or elongate, filiform, serrate, pectinate, or flabellate; inserted on frons in front of eyes, narrowly to widely separated at base. Labrum small, transverse or emarginated anteriorly; mandibles small, curved; maxillary palp with four short and slender, or expanded and truncate palpomeres; gula distinct, gular sutures distinct and separate, mentum mostly quadrate; labial palp with 3 small and slender palpomeres, terminal one truncate or emarginated. Eyes lateral, small to large or reduced. **Pronotum** as wide or wider than head, broadly oval to subquadrate, borders margined laterally, or absent basely; surface smooth, punctate, or rugose; prosternum very short, in some deeply excavated with mesosternum in front for head; procoxal cavities externally

open, internally closed. **Elytra** entire, rarely connate, striae punctate or absent; intervals smooth, punctate, or rugose. Scutellum triangular, small, hidden in some. Legs short to long, with trochantins partially exposed to completely hidden on fore and middle legs; tarsal formula 5-5-5. Abdomen with five, four or three ventrites, strongly reduced in some, sutures entire or obsolete.

In Egypt, the Family Ptinidae is represented by six subfamilies, of them, Anobiinae and Dorcatominae, are studied. According to Alfieri, (1976), Subfamily Anobiinae represented by six species, only one species, *Xystrophorus barbarus* Pic, not present in the Egyptian insect collections, in addition to one species in subfamily Dorcatominae.

Key to the genera and species of Subfamilies Anobiinae and Dorcatominae

- 1- Body round or oval. Antennae with three terminal segments enlarged, asymmetrical, flattened.....**Subfamily Dorcatominae** *Synanobium parmatum*
- Body elongate, cylindrical in shape. Antennae untoothed, last three segments elongate, much longer than previous.....**Subfamily Anobiinae** 2
- 2 (1)-Procoxae touching or very narrowly separated *Oligomerus ptilinoides*
- Procoxae distinctly to widely separated..... 3
- 3(2). Prosternal intercoxal piece V-shaped; punctures of elytral striae obscure, elongate and longitudinally closely spaced..... *Stegobium paniceum*
- Prosternal intercoxal piece parallel-sided, apex not pointed; punctures of elytral striae not as above 4
- 4(3). First abdominal ventrite suture feeble, curving posteriorly in the middle. Lateral margin of pronotum present only in basal half..... *Gastrallus pubens*
- First abdominal ventrite suture distinct, straight or not curving posteriorly in the middle. Tarsal claws each without a basal tooth. Antennomeres 4 through 8 filiform, cylindrical, or subtriangular..... 5
- 5(4). Dorsal surface and legs covered with long and erect hairs. Metasternum not excavate anteriorly; punctures at apical 1/3 of elytra forming distinct striae *Nicobium castaneum*
- Dorsal surface and legs covered with recumbent or short and erect hairs. Abdominal ventrite sutures 2, 3, and 4 evenly distinct throughout. Metasternum deeply excavates anteriorly..... *Anobium punctatum*

Subfamily Anobiinae

Diagnosis: Hind coxae elongate with a furrow along their rear margin into which the hind femur can be inserted lengthways. Metasternum and the first segment of the abdomen on different levels and without grooves to accommodate the middle and hind legs. The shape more elongated, oval or rounded with a smooth outline. Antennae slim, the last three segments elongate, much longer than those before them. Sides of the pronotum with a border, at least in the rear half. Prosternum hollowed out at the front to accommodate the head.

Genus *Anobium* Fabricius, 1775

***Anobium* Fabricius, 1775:** Systema entomologiae, sistens insectorum classes, ordines, genera, species, adiectis synonymis, locis, descriptionibus, observationibus. Flensburgi et Lipsiae: Korte, p. 62

***Byrrhus* Müller, 1776:** Zoologiae Danicae prodromus, seu animalium Daniae et Norvegiae indigenarum characteres, nomina et synonyma imprimis popularium. Hafniae: Hallageriis, p. xxii.

Type species *Anobium punctatum* DeGeer, 1774

Generic diagnosis:

Body surface with short hairs. Antennae filiform, with eleven segments, the three last segments considerably lengthened. Pronotum with tubercles, the sides completely bordered (rarely shortly interrupted in the middle). Elytra thickened, short, and provided with hairs and stripes of punctures. Front coxae divided from one another. Ventral surface with a deep hollow between the middle coxae, which extends through the whole of the mesosternum and

almost all of the metasternum and is steep at the sides. The first segment of abdomen ventrally longer than the third.

Diagnosis: Length 2.5-5.0 mm. cylindrical body, Pale or dark brown colored. Upper surface densely hair with a slight silky sheen; the hairs on the elytra usually give a stripy appearance. Antennae more elongate (in males segments 9-10 together are as long as segments 1-8 combined); the middle segments of the antennae are as rounded on the inner as on their outer surface. Head and eyes are invisible beneath the thorax. Elytra with parallel sides, covered with fine yellowish hairs and longitudinal rows of pits. Vestiture of dorsal surface and legs recumbent or with short erect setae; Antennae 4-8 filiform, cylindrical, or subtriangular.

***Gastrallus* J.du Val, 1860:** Description de deux espèces nouvelles. Glanures Entomologiques 2. P. 142.

Type species *Anobium immarginatum* Miiller, 1821

Generic diagnosis:

Body cylindrical, short, covered with dense pubescent. The surface completely, or at sides only, covered with lighter hairs, in addition to regular rows of pits. Antenna with the three last segments strongly elongated and flattened. Pronotum with a lateral margin well developed in basal half only. Anterior margin of prosternum with distinctly impressed between coxae. Prosternal intercoxal piece parallel-sided, apex not pointed.

Diagnosis: body length: 2.5 mm, pronotal length: 0.6 mm, pronotal width: 1.1 mm, elytral length: 2.0 mm, elytral width: 0.7 mm. Color deep brown to reddish. Antenna with the last three segments Combined much longer than preceding five segments. Body dorsally covered with a mix of long hairs and fine hairs. Punctures of elytral striae obscure, elongate, and longitudinally closely spaced. Procoxae distinctly separate. Prosternal process V-shaped. Prothorax ventrally concave to excavate beneath, more or less enclosing head.

Material examined: (1) Tawfikia (Behera), 15.X. 1924 (ALFC).

Subfamily Dorcatominae

Diagnosis: Body short, oval and strongly convex. Antennae 11-segments, serrate type with three last segments enlarged, asymmetrical and flattened. Eyes near the base slightly dented. Hind coxae elongate with a furrow along their rear margin into which the hind femur can be inserted lengthways. Metasternum and the first segment of the abdomen on different levels. Metasternum and the front of the first segment of the abdomen with grooves to accommodate the middle and hind legs, these grooves with a sharply raised edge.

***Synanobium* Schilsky, 1898:** Die Käfer Europa's. Nach der Natur Beschrieben. Heft 35. Nürnberg: von Bauer und Raspe (E. Küster). P. 22.

Type species: *Synanobium ganglbaueri* Schilsky, 1898 (= *Rhadine parmatum* Baudi di Selve, 1874)

Generic diagnosis:

First, ventrite depressed or grooved for reception of hind legs, posterior margin frequently distinctly carinate or appearing raised above second ventrite. During body retraction procoxae visible. Metasternum produced into a broadly rounded lobe, grooved laterally for mesotarsi, and which nearly conceals mandibles during retraction. Second ventrite approximately as long as third through fifth combined.
